A semiconductor is defined as a material whose conductivity falls intermediate between that of metals, 10^6 to 10^8 ohm $^{-1}$ m $^{-1}$, and that of dielectrics (insulators); 10^{-20} to 10^{-8} ohm $^{-1}$ m $^{-1}$. Semiconductors are materials which have resistivity between 10^{-5} to about 10^7 ohm-m (at ordinary temperature).

Semiconductors: Meaning and Classification | Electrical ...

Semiconductors are materials that have conductivity in-between conductors and insulators. They can block or allow the current flow providing total control over it. They are mostly modified by adding impurities called doping. It modifies its properties like unidirectional current flow or amplification or energy conversion etc.

Conductivity of semiconductor materials increases with temperature, as an increase in temperature causes increase in conduction current. This is due to increase in broken covalent bonds that result in more charge carriers for current flow. So more electrons from Valence Band jump to Conduction Band with increase in temperature.

Books Tyagi wrote one internationally acclaimed book Introduction to Semiconductor Materials and Devices, which is widely used in Electrical Engineering, semiconductor devices and material science undergraduate and postgraduate courses. It was published by John Wiley & Sons on 7 March 1991.

Man Singh Tyagi - Wikipedia

A semiconductor material has an electrical conductivity value falling between that of a conductor, such as metallic copper, and an insulator, such as glass. Its resistivity falls as its temperature rises; metals are the opposite.

There are two different types of semiconductors possible. One is called N-type material, and the other, P-type material. Unsurprisingly, the N stands for Negative and the P stands for (you guessed it) Positive. N-type material is created by adding pentavalent impurities, that is, a dopant with five electrons in its outer shell.
